# Real-time satellite data based service for fires monitoring

Potapov Georgy, RDC ScanEx

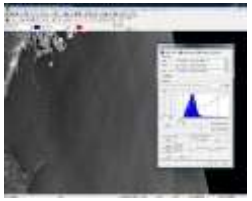

# Web-services is just a way, user can get access to the spatial intelligence

## RDC SCANEX process flow

Ground receiving station

Data processing (automatically, by expert)

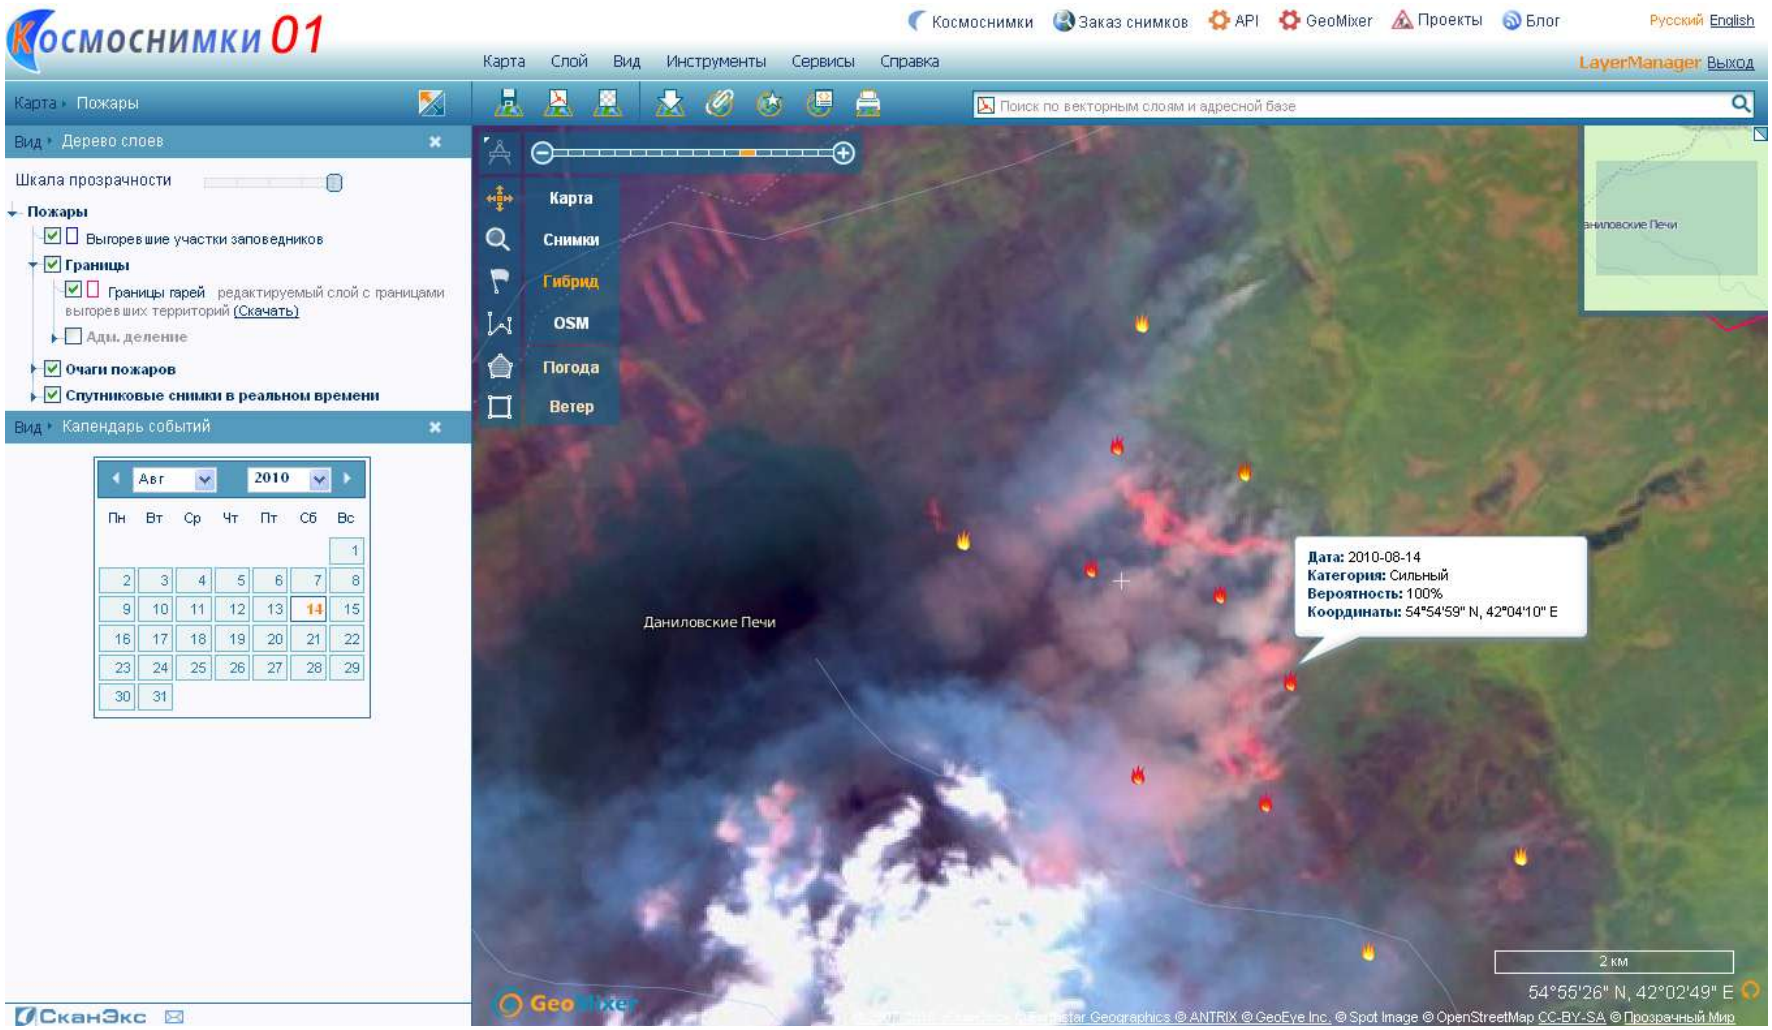

Web-GIS to publicize data and deliver it to the end-user

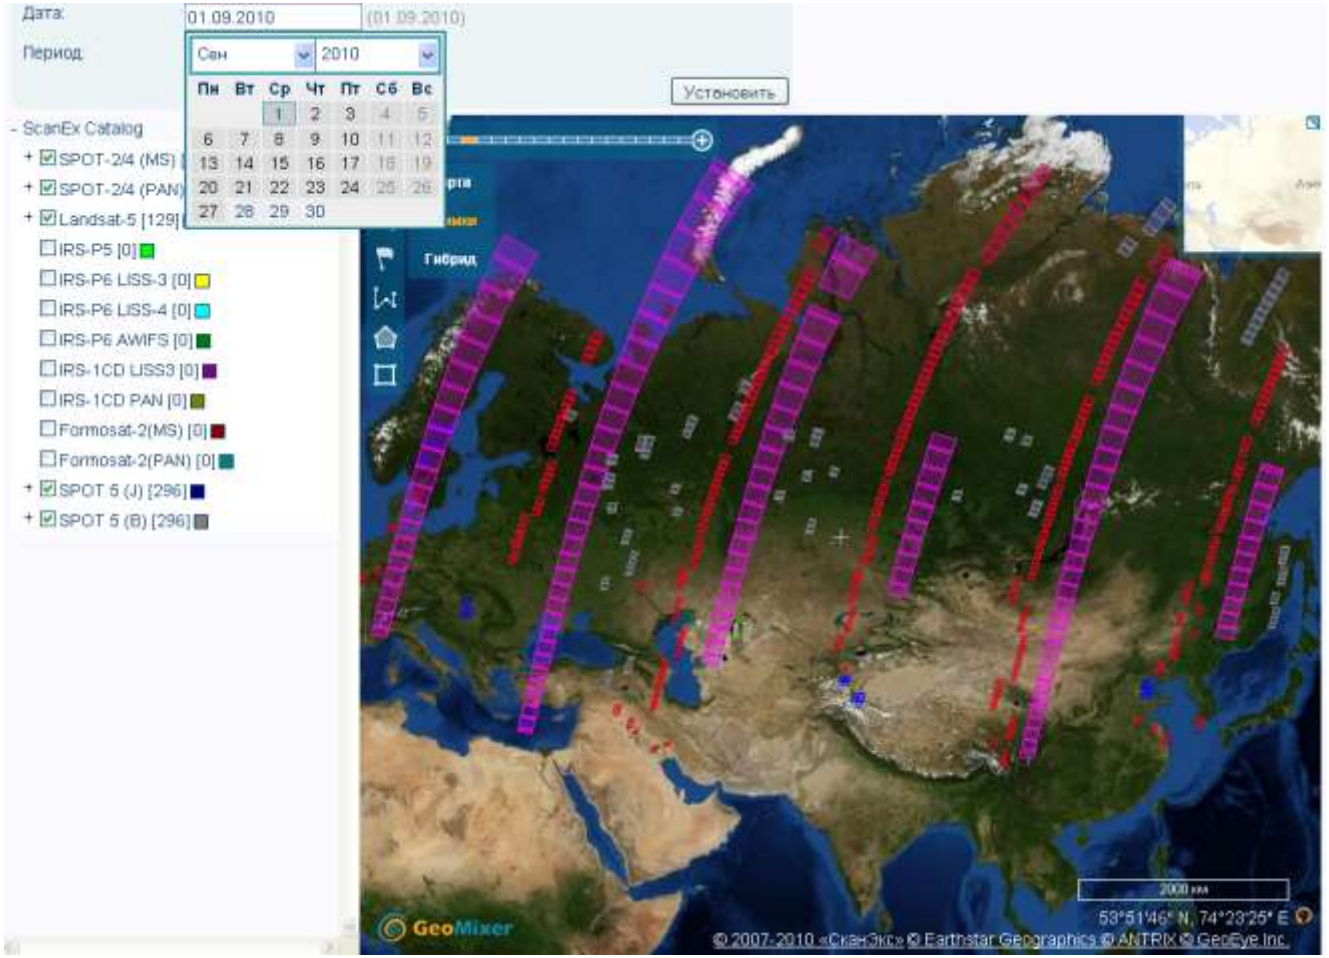

# Emergency response

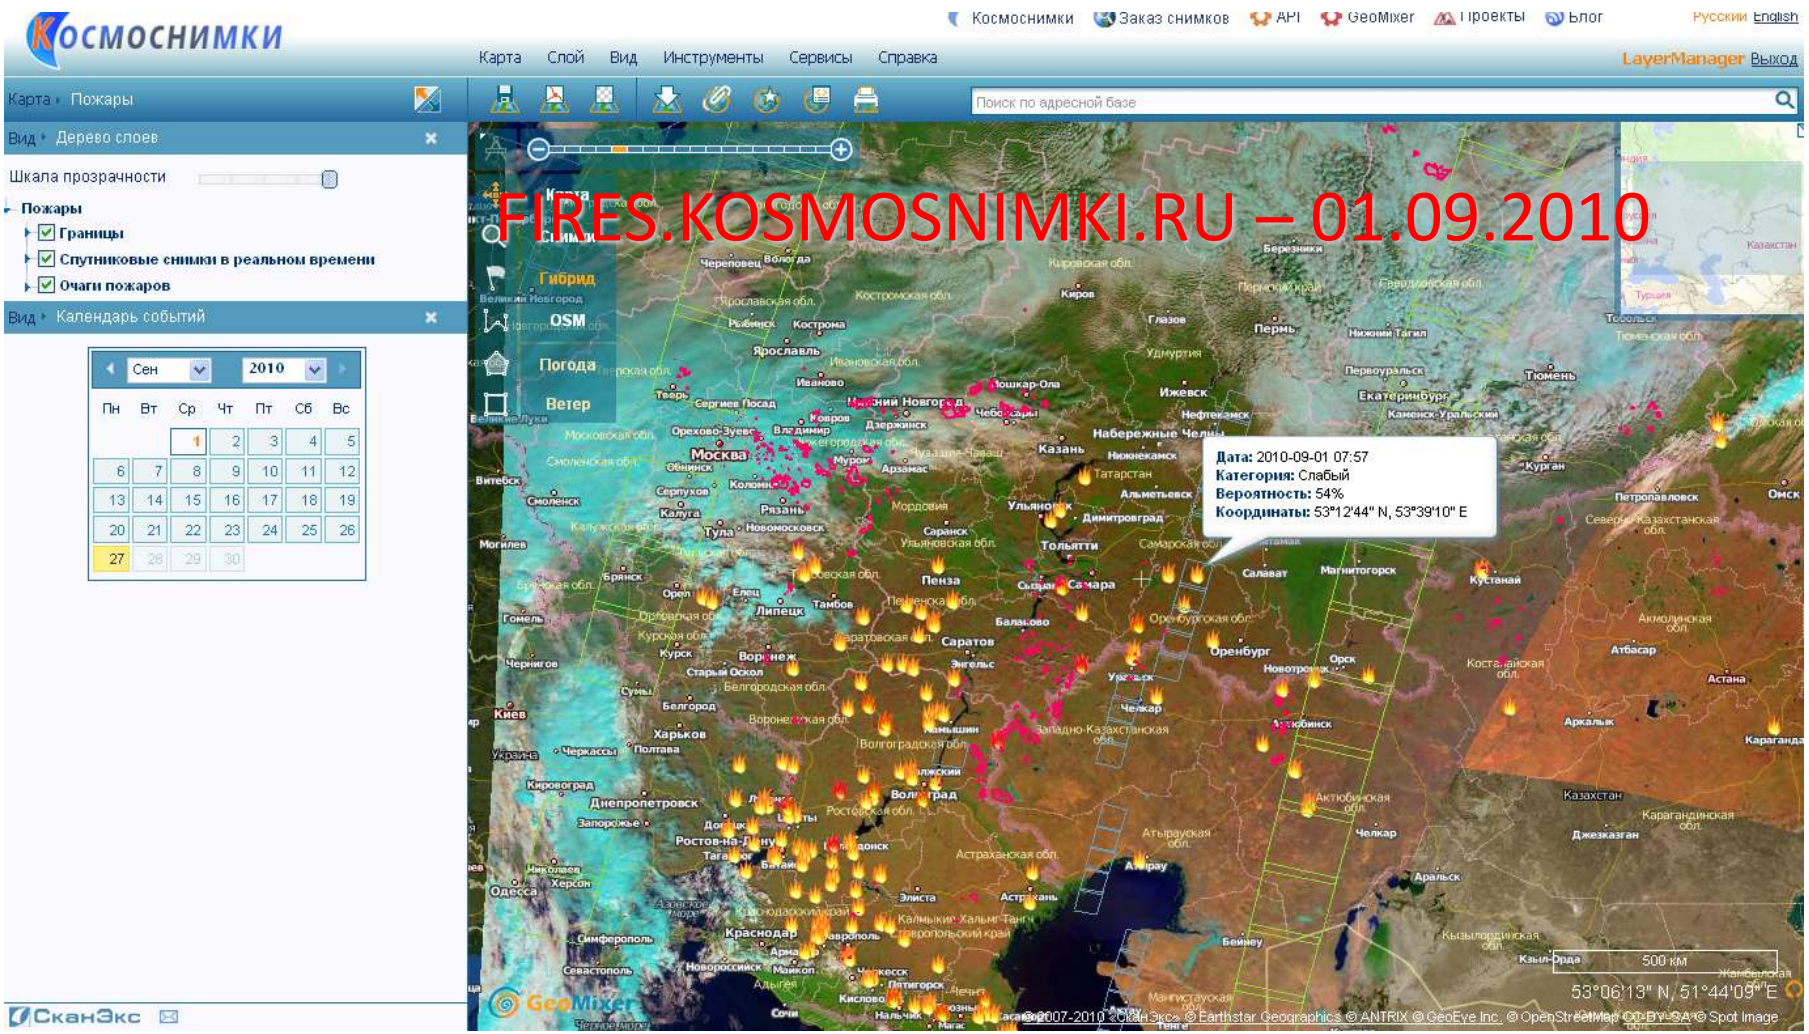

# Fires monitoring service

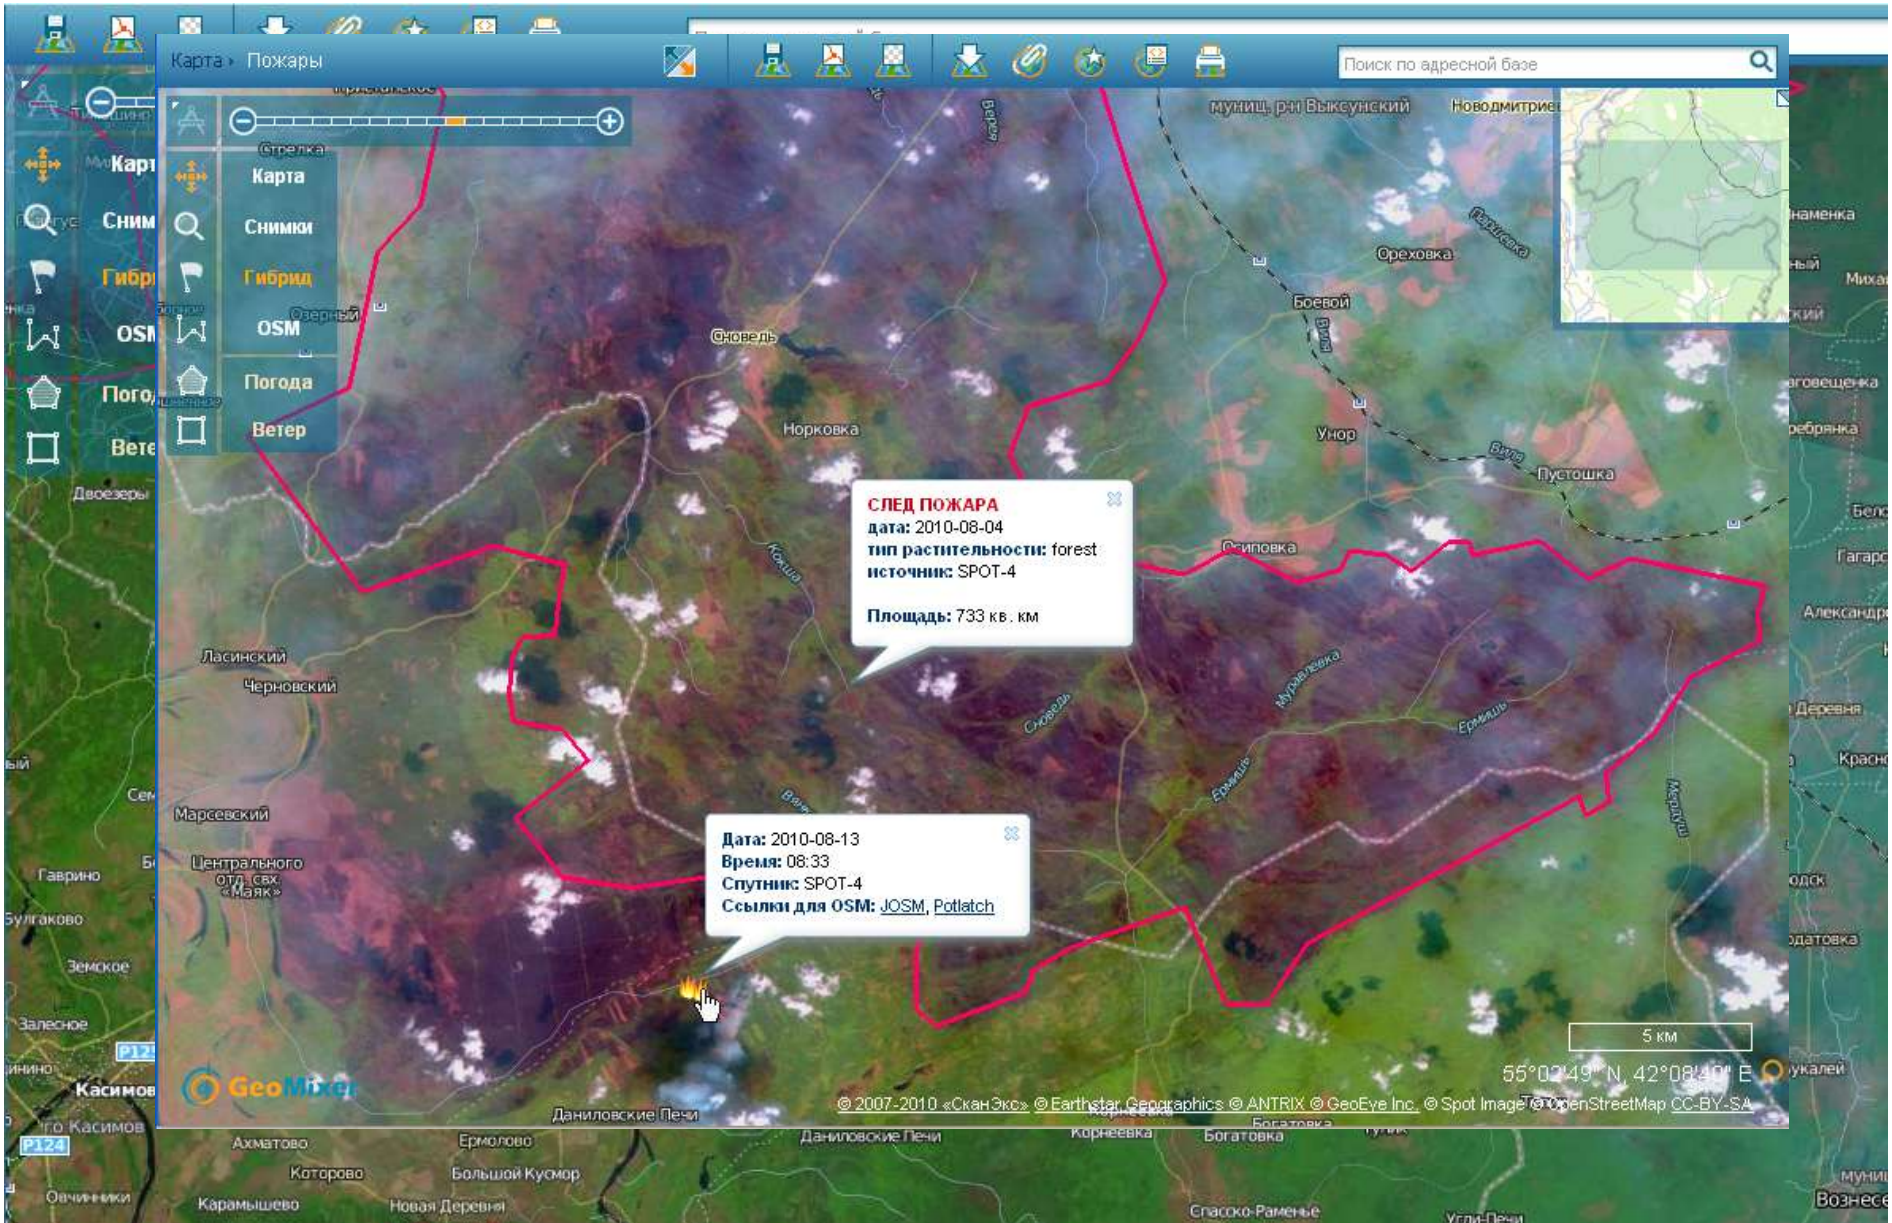

# All data for one day, collected by the network of ground receiving stations

# All data, collected for one day (01.09.2010)

# mapping burnt areas on the basis of more detailed satellite images

# Integration of images in OSM editor applications

6. Outline the burnt place. To start outline, click the canvas, to end it, click the first node.
   Tag it as either landuse=forest or landuse=field plus the tag specifying the date of fire: burnt=YYYY-mm-dd, where YYYY-mm-dd is the date

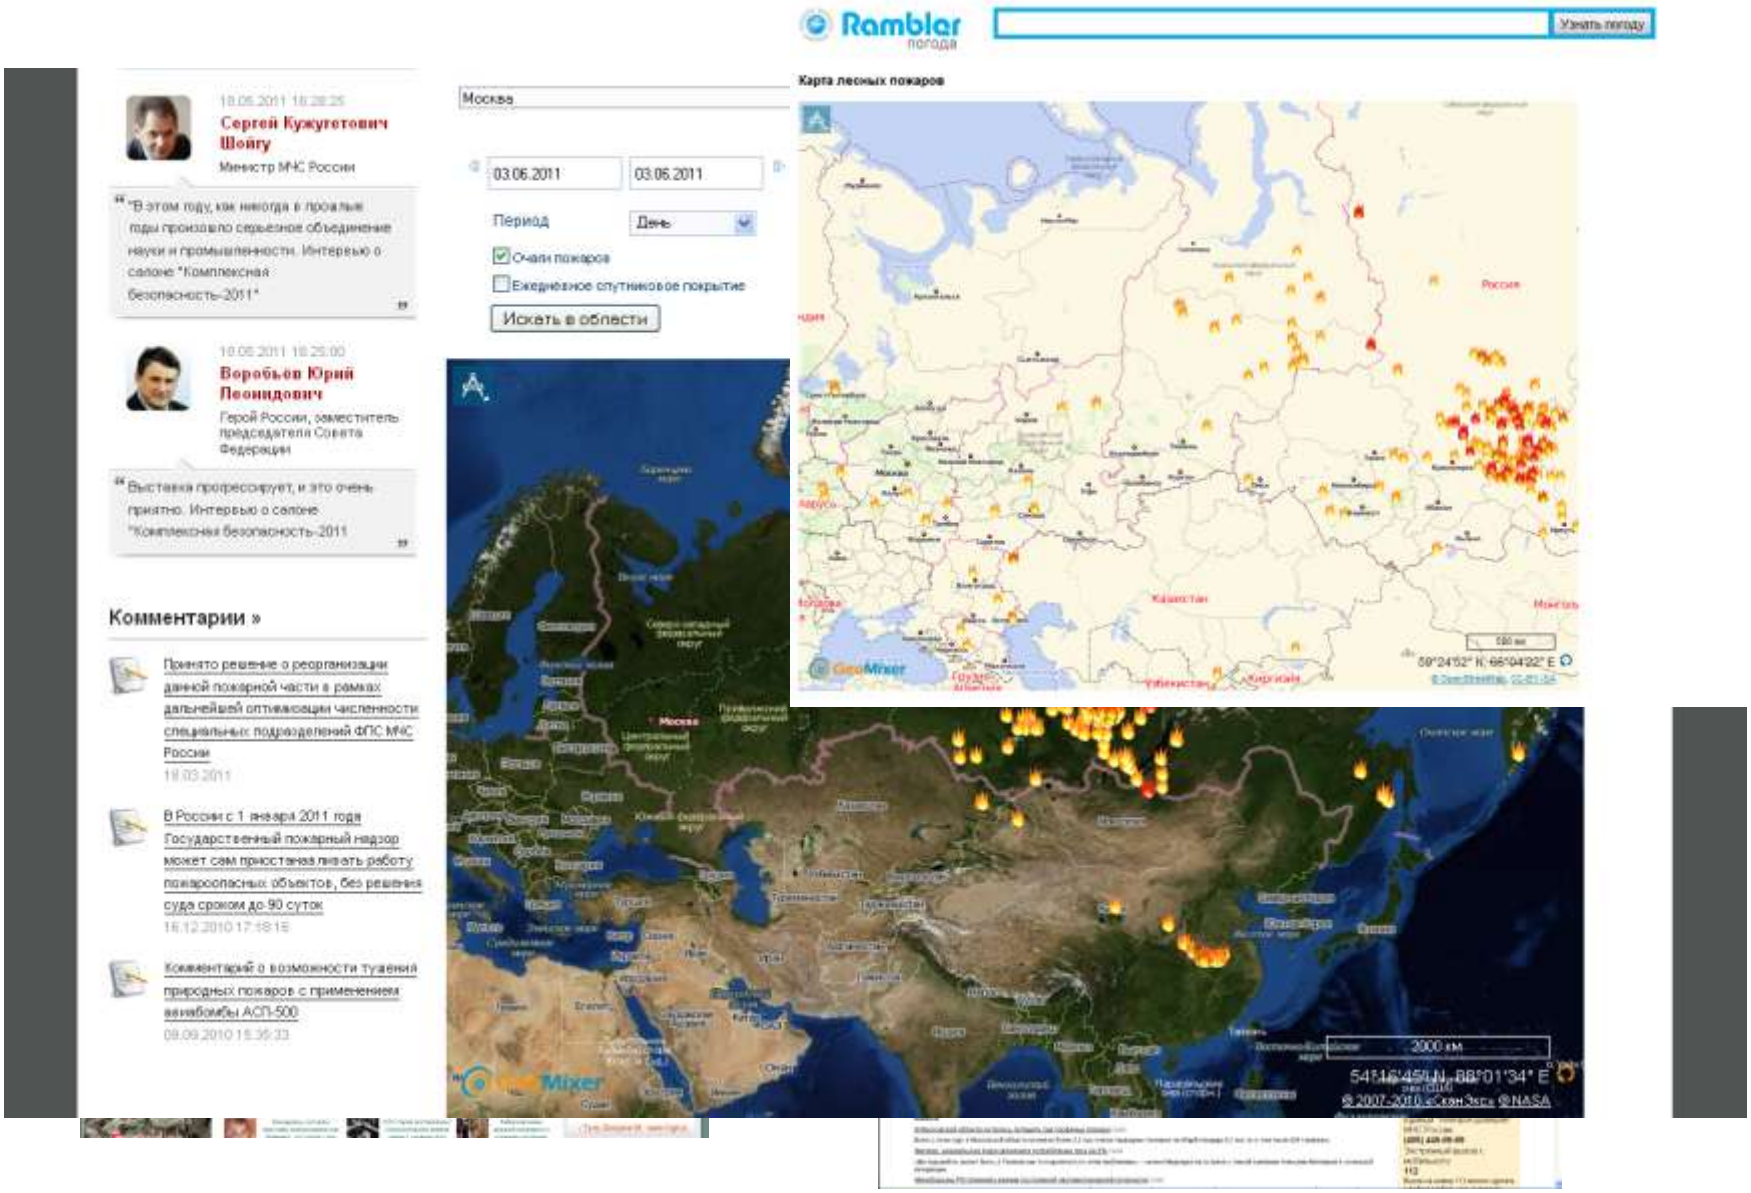

7. When you've mapped everything, don't forget to save your work. Feel free to add a changeset comment "Outlined from fires.kosmosnimki.ru
   Wait until the upload process completes. If you have enough skills, you can map everything else you see around, including fields and woods however.

# Clusters points and Automatic fires outlines

# The information must be available for third-party services and applications

# As a conclusion

The fastest and the easiest way data can be delivered to the end-user is to publish it on the Web

The limitations are the following: the bandwidth, the format, the availability  of Internet

Operational monitoring services enable establishing access to the spatial intelligence in near real-time mode and in the form most demanded by users

OSM has a very strong and flexible architecture to put the UGC data in and a great potential to use a power of community for crowdsourcing projects

# Thank you for your attention!
